Obtain Data Replication

Data Replication is a tool for replicating (selected) master data between legal entity and to external systems. To minimize performance impact, native SQL Change Tracking is used to track which data needs to be replicated.

Known issues

- Master data is not consistent across legal entity and systems (PIM, webshop, warehouse, etc.).
- Maintaining data in several different legal entity and systems.
- Starting up a new legal entity is a comprehensive task.

Gain control of the data

- Ensuring data consistency.
- Defining a master legal entity ensures that there is a single source of truth for core data.
- The generation of security privileges ensures consistency between the data being replicated and the data that can be modified locally.

Ensuring data consistency

- Setup per destination of which records and fields should be replicated.
- Generation of security privileges based on field configuration.
- Setup of conversion.
- Generate replication setup based on a screen or an entity.
